

Random changepoint mixed segmented regression with smooth transition: an example with lateral amyotrophic sclerosis data

Julio M. Singer

Universidade de São Paulo

We consider random changepoint mixed segmented regression models to analyze data obtained from a study conducted to verify whether treatment with stem cells may delay the onset of a symptom of amyotrophic lateral sclerosis in genetically modified mice. The proposed models capture the biological aspects of the data, accommodating a smooth transition between the periods with and without symptoms.

An additional changepoint is considered to avoid negative predicted responses.

Given the non-linear nature of the model, we adapt an algorithm proposed by Muggeo et al. (2014, *Statistical Modelling*) to estimate the fixed parameters and to predict the random effects by fitting linear mixed models at each step.

We compare the variances obtained in the final step with bootstrapped ones.

We also conduct a simulation study to evaluate the difference between the estimates of the fixed model parameters (associated to "typical subjects") and corresponding population averaged parameters.
